

# **Renewable Energy Lab Weather Station**

**By:**

**Chenxi Dong, Rowan McCullough, Ian Torp, and Shutong Wang**

# Project Description

The goal of this project is to make a weather station for the RE Lab at NAU that will last for years. This station will provide accurate and current measurements for various weather conditions and will be accessible from anywhere with an internet connection.

Measure:

- Temperature
- Humidity
- Wind Speed/Direction
- Barometric Pressure
- Solar Irradiance

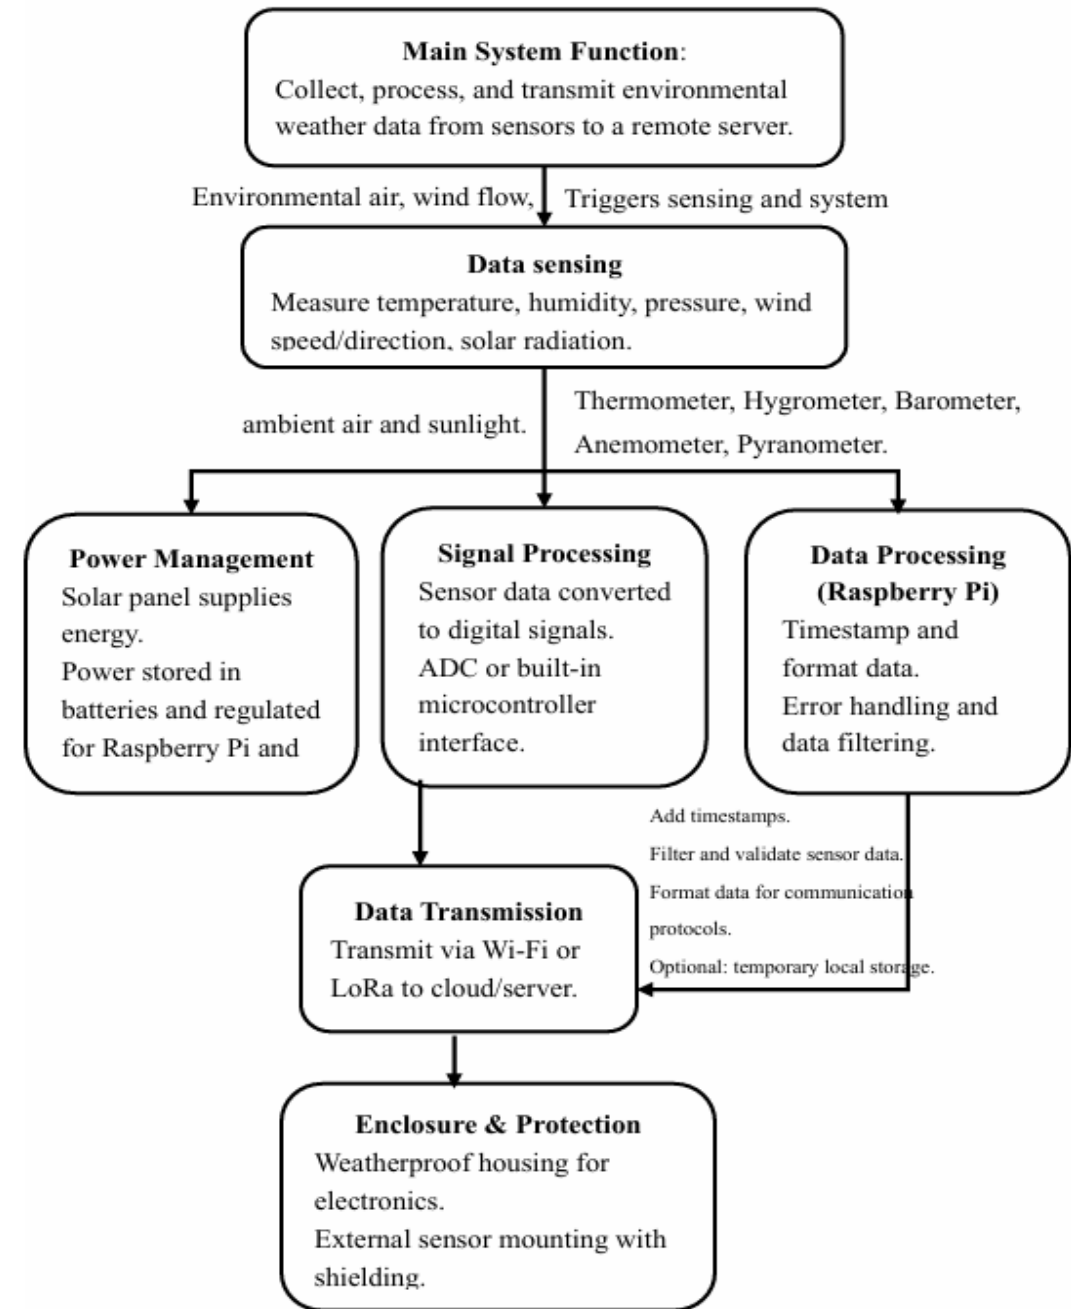

Purpose:

For academic use within the Wind Power and Renewable Energy courses. Weather stations are important for weather forecasts, disaster preparedness, and agricultural information.

# Design Description

The system function diagram outlines the weather station's workflow, organizing it into essential components: sensing, power supply, signal conversion, data processing, transmission, and enclosure. It visualizes how environmental input triggers sensor readings, which are digitized, processed by a Raspberry Pi, and sent to remote servers. The diagram highlights key interactions between modules, identifies technical needs like timestamping, ADC integration, and energy regulation, and reinforces a modular architecture to support reliable operation, remote updates, and component replacement.

# Design Description

This Python-based script enables real-time monitoring and visualization of environmental data from the BME280 sensor using a Raspberry Pi. The system captures temperature, humidity, and barometric pressure through the I2C interface.

The core functionality includes:

- **Sensor Initialization:** The I2C bus is initialized via `smbus2`, and calibration data is loaded using the `bme280` library to ensure accurate readings.
- **Data Acquisition Loop:** The code continuously samples the sensor at 1-second intervals, capturing temperature (°C), relative humidity (%), and pressure (hPa) along with a timestamp.
- **Live Plotting:** The data is plotted in real time using `matplotlib`, displaying three vertically stacked subplots for each variable. Interactive mode allows for continuous updates without restarting the graph.
- **Data Logging:** Sensor values and timestamps are stored in lists, which can be later saved or analyzed.
- **Interrupt Handling:** The loop gracefully exits when a key board interrupt is detected, ensuring a clean shutdown and final display of the plots.

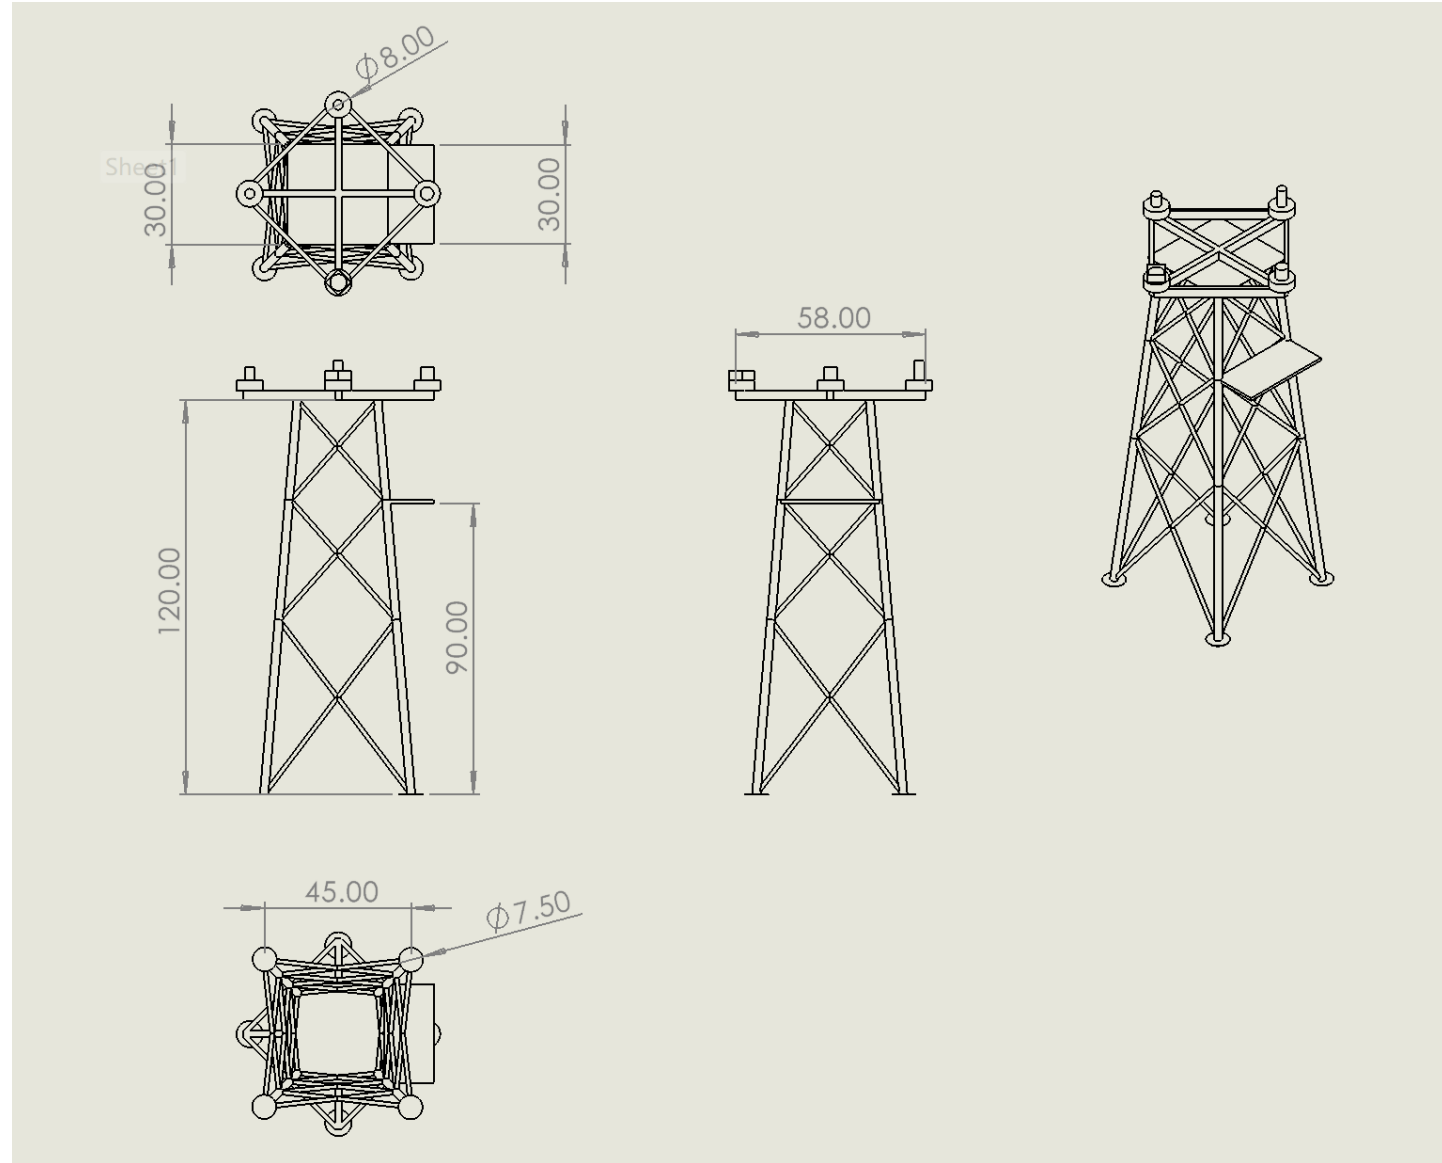

To run the script, the following Python libraries are used and must be installed in a virtual environment:

- `smbus2` – for I2C communication
- `bme280` – for sensor calibration and sampling
- `matplotlib` – for dynamic plotting

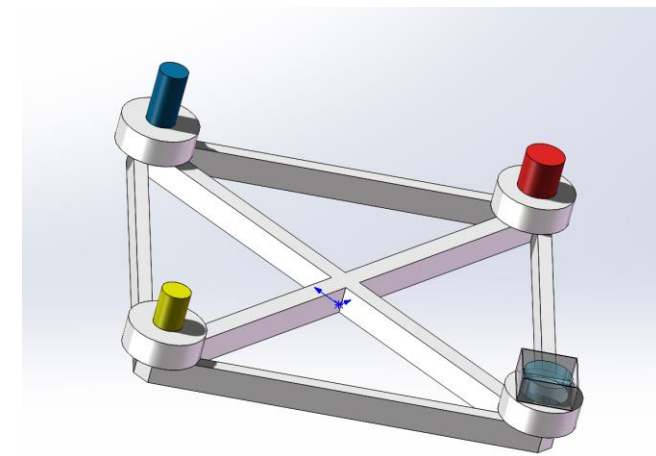

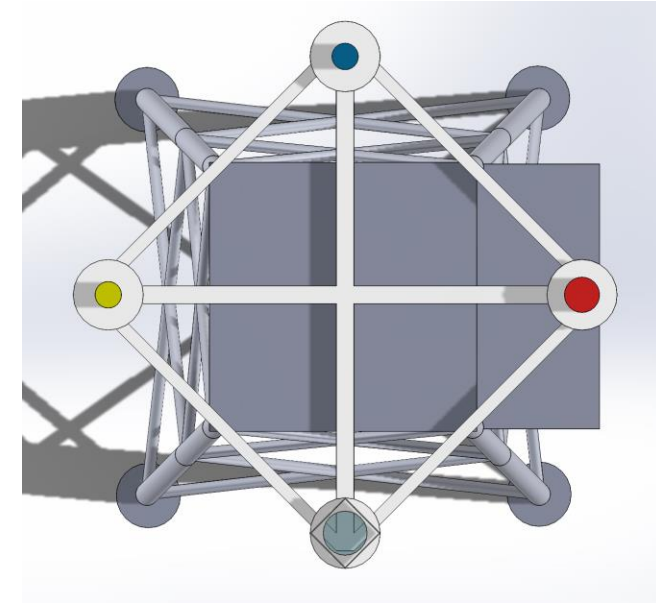

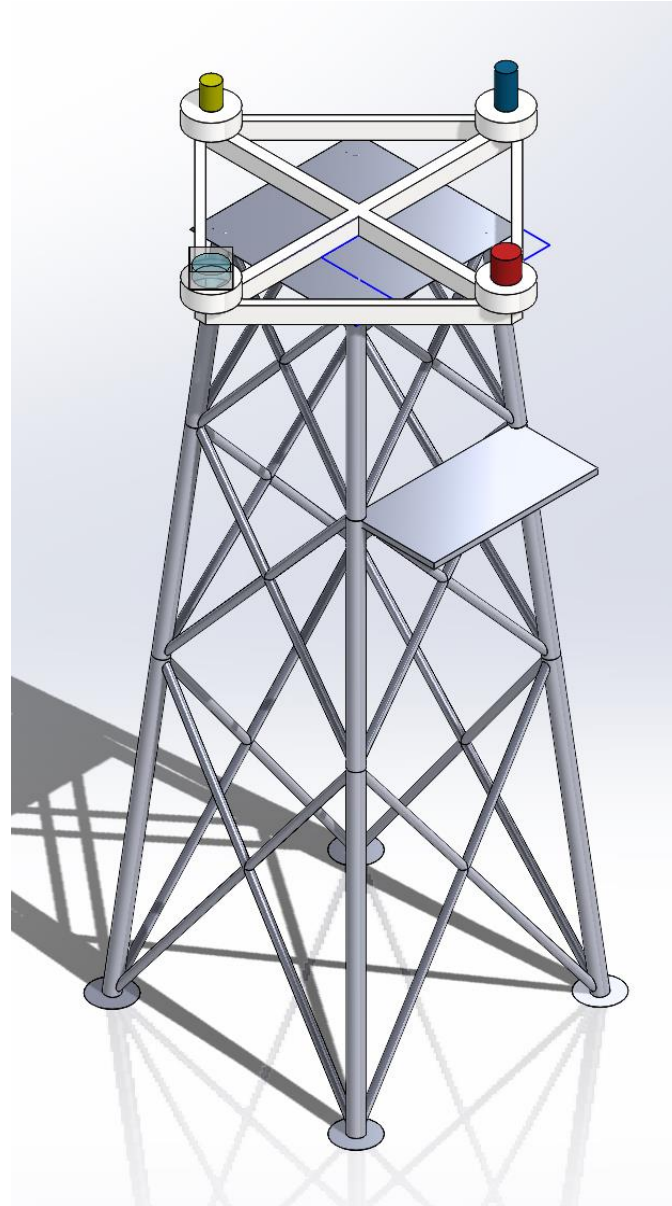

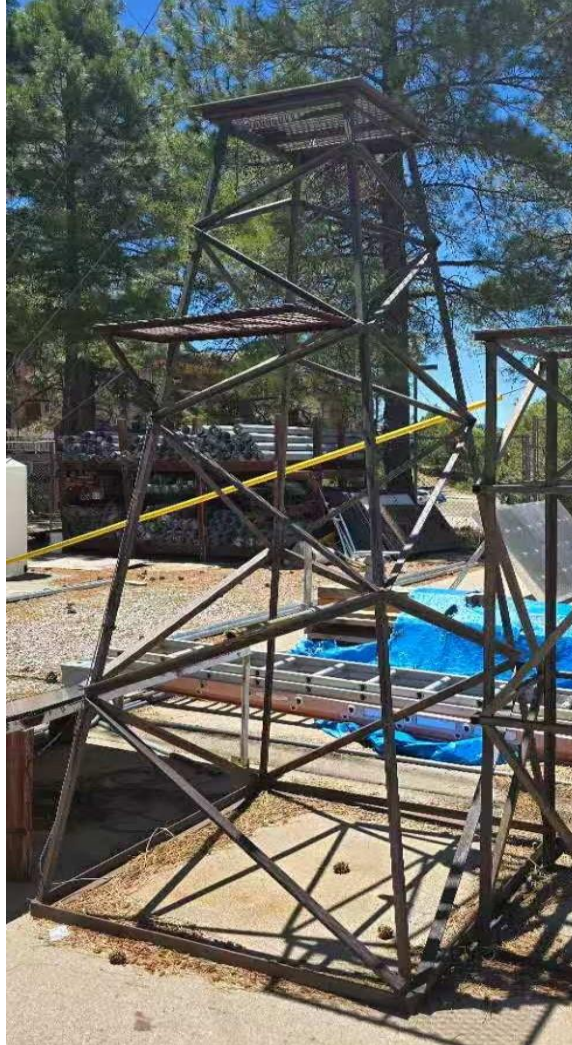

# Design Description

## Main Tower

- Units in Inches
- Total height is 120 inches
- Top frame width is 58 inches (corner to corner)
- Base width is 45 inches

# CAD

# Design Requirements

## Customer Requirements:

- Measurement of Key Weather Parameters - Station will measure temperature, humidity, wind speed and direction, barometric pressure and solar irradiance.
- Data Transmission - Data collected will be transmitted via internet
- Remote Data Access - Live and stored data should be accessible through a web interface
- Renewable Power Supply - Any components which require power must run on solar energy
- Weather Durability - Station must withstand outdoor weather conditions
- Low Maintenance - Station should require less than 2 hours of maintenance per year
- User Friendly - User interface should be easily navigable
- Ease of Installation - Installation should require minimal tools or training
- Low Cost - Station should be cost effective and within budget
- Safety Compliance - Must comply with relevant electrical and operational safety standards
- Data Storage - Data should be stored in an accessible and organized database for at least one year.

## Engineering requirements:

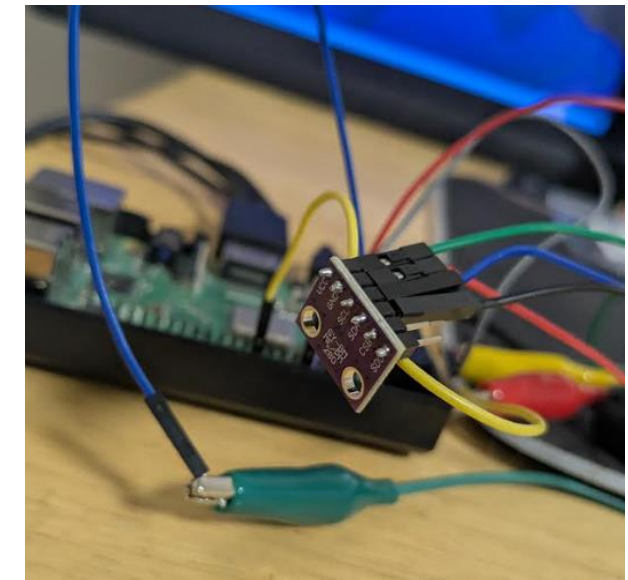

- Long Term Data Storage - Database should log data in an organized manner over the course of 4 years
- Increased Data Accuracy - Sensor readings should be highly accurate, within 3% or less. Data average calculations should be properly computed
- Multiple Wind Speed Readings - Wind speed and direction should be measured at both standard height and atop existing tower at lab providing at least 2 readings.
- Measured at Industry Standards - Sensors should be properly positioned according to industry standards
- Proper Calibration - Sensors should be properly calibrated to upload accurate data from raw readings within 3% of true values
- Measurement of All Data Types - Station should record 5 data types including temperature, pressure, humidity, solar irradiation and wind data
- Low Power Requirement - Station should be capable of fully operating under existing solar generated power means located at lab, with a target of 0.2 kWh per day or less.

# Engineering Calculations

Parameter	Value
Ambient Temperature $T_a$	35°C (typical summer)
Solar Irradiance $G$	800 W/m <sup>2</sup> (clear sky, noon)
Enclosure Absorptivity $\alpha$	0.85 (black plastic)
Surface Area $A$	0.015 m <sup>2</sup> (top of enclosure)
Conv. Coefficient $h$	10 W/m <sup>2</sup> ·K (natural convection)
Emissivity $\varepsilon$	0.9

$$Q_{\text{solar}} = \alpha \cdot G \cdot A = 0.85 \times 800 \times 0.015 = 10.2 \text{ W}$$

$$Q_{\text{loss}} = Q_{\text{conv}} + Q_{\text{rad}}$$

$$Q_{\text{conv}} = h \cdot A \cdot (T_s - T_a) = 10 \cdot 0.015 \cdot (65 - 35) = 4.5 \text{ W}$$

$$Q_{\text{rad}} = \varepsilon \cdot \sigma \cdot A \cdot (T_s^4 - T_a^4)$$

$$= 0.9 \cdot 5.67 \times 10^{-8} \cdot 0.015 \cdot (338^4 - 308^4) \approx 4.0 \text{ W}$$

$$Q_{\text{loss, total}} \approx 8.5 \text{ W} < Q_{\text{solar}} = 10.2 \text{ W}$$

- Net heat gain  $\approx 1.7 \text{ W}$
- Enclosure surface temperature may rise above 65°C
- Inside enclosure, electronics may reach >75°C

## Thermal Durability Analysis

We simulate how the outer surface of a small electronics enclosure heats up under constant solar irradiance of 800 W/m<sup>2</sup>

Component	Max Safe Temp	Est. Internal Temp	Risk Level
Raspberry Pi 3B	85°C	~75°C	Medium
NRG BP-20 Sensor	80°C (est.)	~70–75°C	Low–Medium
MCP3008 ADC	85°C	~73°C	Low

Through research, sensors can reach 75 degrees Celsius in a short period of time.

Conclusion : The enclosure is at moderate thermal risk under summer conditions. Recommend adding ventilation openings or applying reflective coating to reduce solar absorption.

# Engineering Calculations

Obtained Calibration Certificates with specific calibration constants using Serial Numbers from NRG and LI-COR Websites.

## Calibration Constant(s):

Output: 71.12 microamps per 1000 watts m<sup>-2</sup>

## For use with LI-COR handheld meters and loggers:

Multiplier: -14.06 watts m<sup>-2</sup> per microamp

## If this is an LI-200-BL (3-wire bare leads):

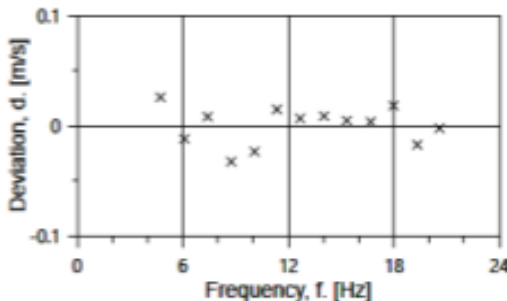

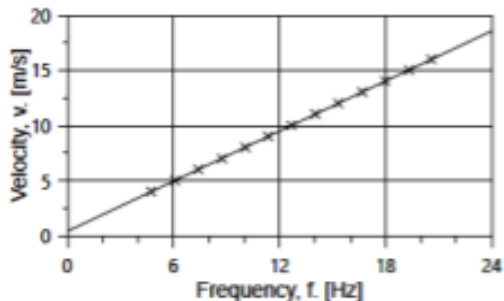

Multiplier: 14.06 watts m<sup>-2</sup> per microamp

## For use with LI-COR 2220 (147 ohm) millivolt Adapter:

Multiplier: -95.65 watts m<sup>-2</sup> per millivolt

## If this is an SL or SMV sensor:

Multiplier: -100 watts m<sup>-2</sup> per millivolt

# Engineering Calculations

## Sampling Frequency & Total Samples

- Sampling interval = 30 s
- Samples per year:  

$$\frac{60}{30} \times 60 \times 24 \times 365 = 1051200 \text{ samples/year}$$

Based on this frequency of use, check manufacturer information and community resources.

					Sensor	Model	Manufacturer	Datasheet / Industry Note
					Humidity	<b>BME280</b>	Bosch Sensor tec	Designed for long-term operation, but MEMS sensors show performance drift after 1 year of continuous high-frequency use.
					Anemometer	<b>NRG #40C</b>	NRG Systems	Calibrated annually; field use up to 5+ years with proper lubrication and bearing maintenance.
Sensor	Samples/day	Samples/year	Calibration Interval	Replacement Cycle				
<b>BME280</b>	2,880	1,051,200	—	12 months	Pyranometer	<b>LI-200R / MS-60</b>	LI-COR / EKO	Manufacturer recommends calibration every 1–2 years; replacement after ~5 years.
<b>NRG #40C</b>	—	—	12 months	3–5 years				
<b>LI-200R / MS-60</b>	2,880	1,051,200	1–2 years	5 years	Barometer	<b>BP60C</b>	NRG Systems	Annual calibration recommended; typical lifespan 3–5 years.
<b>BP60C</b>	2,880	1,051,200	1 year	3–5 years

PI Data Conversion	Coding issue	Invalid data	Bug in coding, unrecognized input data	20	Extensive Code Testing
PI Data Upload	Loss of Internet	Missing data	Internet down, LAN connection failure	16	Database Check, Wired Connection
Truss Supports	Fatigue Failure	Broken Sensors	Poor mounting or durability	9	Secure mounting, strong material

# Design Validation

## Test Methods:

- Comparison of our data against Pulliam airport weather data
- Calibration tests using controlled conditions such as ice water at 0 degrees to test temperature sensor
- Visualization of data to spot outliers
- Measure energy usage
- Secure wire connections and make sure they are not easily disconnected by weather or tampering
- Ensure proper sensor housing which aligns with industry standards
- Ensure snow buildup will not pose a threat to sensor data collection
- Analyze data difference between 10m anemometer and 30m anemometer.

# Design Validation

## Testing Equipment and Resources:

- Reference Weather Data: Pulliam Airport historical weather records (public data access)
- Power Supply: Rechargeable batteries and regulated USB-C output for Raspberry Pi
- Data Logger: Raspberry Pi 3B with SD card for data storage
- Thermal Chamber / Freezer (optional): For extreme temperature tests
- Multimeter & Voltage Logger: To monitor energy usage and wire integrity
- Spare Sensors: For redundancy and comparison
- Outdoor Testing Space: Open area to mount weather station at different elevations (10m and 30m poles)
- Weatherproof Mounting Kits: To simulate snow or wind loading on sensors
- Coding & Visualization Tools: Python/MATLAB for plotting and regression
- Internet Access: To test upload reliability and simulate failure conditions

# Schedule

# Budget

~\$3000 worth of existing equipment.

Around ~\$500 from client for expected additional costs.

\$300 have been contributed by the team to meet the fundraising goal

Additional expenses:

- Construction of diamond crossbar for mounting
- Additional sensor parts i.e. voltage amplifiers,

# Fundraising

\$300 total from the team

\$75 from each person

Total remaining to spend:

\$263.64

# Thank You & Questions?

# Prototype 2

[illegible]

The screenshot shows a Jupyter Notebook interface with a file explorer at the top displaying 'bme280\_sensor.py'. The notebook contains the following Python code:

```

1 import smbus2
2 import time
3 import math
4 import matplotlib.pyplot as plt
5 from datetime import datetime
6
7 #BME280 address
8 address = 0x76
9
10 #Initialize I2C bus
11 bus = smbus2.SMBus(1)
12
13 #Calibration parameters
14 calibration_params = bme280.load_calibration_params(bus, address)
15
16 #Lists
17 timestamps = []
18 temperature_celsius_values = []
19 humidity_values = []
20 pressure_values = []
21
22 running = True
23
24 #Exit
25 plt.ion()
26 fig, axs = plt.subplots(2, 1, sharex=True, figsize=(16,8))
27 fig.suptitle('SoS-iTee Sensor Readings')
28
29 #Labels
30 axs[0].set_ylabel('Temperature (°C)')
31 axs[1].set_ylabel('Humidity (%)')
32 axs[2].set_ylabel('Pressure (hPa)')
33
34 #Loop forever
35 while running:
36     try:
37         #read data
38         data = bme280.sample(bus, address, calibration_params)
39
40         #Extract data and timestamp
41         temperature_celsius = data.temperature
42         humidity = data.humidity
43         pressure = data.pressure
44         timestamp = data.timestamp
45
46         #Put in lists
47         timestamps.append(timestamp)
48         temperature_celsius_values.append(temperature_celsius)
49         humidity_values.append(humidity)
50         pressure_values.append(pressure)

```

```

51 pressure_values.append(pressure)
52
53 #plot
54 for i, (ax, values, label) in enumerate(zip(axes, [temperature_celsius_values, humidity_values, pressure_values],
55                                             ['Temperature (Celsius)', 'Humidity (%)', 'Pressure (hPa)'])):
56     ax.clear()
57     ax.plot(timestamps, values, label=label)
58     ax.legend()
59     ax.set_ylabel(label)
60
61     axes[i].set_xlabel('Time')
62
63 fig.autofmt_xdate(rotation=45)
64 plt.pause(1) #pauses to update plot
65
66 time.sleep(1)
67
68 except KeyboardInterrupt:
69     print('Program stopped')
70     running = False
71 except Exception as e:
72     print('An unexpected error occurred:', str(e))
73     running = False
74
75 #close plot
76 plt.ioff()
77 plt.show()
78

```
